A distributed deployment model for Encrypted Client Hello

Ted Johnson

Supervisor: Dr Stephen Farrell

April 2024

A dissertation submitted in partial fulfilment
of the requirements for the degree of
Master in Computer Science (MCS)

Declaration

I hereby declare that this dissertation is entirely my own work and that it has not been submitted as an exercise for a degree at this or any other university.

I have read and I understand the plagiarism provisions in the General Regulations of the University Calendar for the current year, found at <http://www.tcd.ie/calendar>.

I have completed the Online Tutorial on avoiding plagiarism 'Ready Steady Write', located at <http://tcd-ie.libguides.com/plagiarism/ready-steady-write>.

I consent / do not consent to the examiner retaining a copy of the thesis beyond the examining period, should they so wish (EU GDPR May 2018).

I agree that this thesis will not be publicly available, but will be available to TCD staff and students in the University's open access institutional repository on the Trinity domain only, subject to Irish Copyright Legislation and Trinity College Library conditions of use and acknowledgement. **Please consult with your supervisor on this last item before agreeing, and delete if you do not consent**

1 Introduction

Encrypted Client Hello (ECH) is a proposed extension to the Transport Layer Security protocol version 1.3 (TLS 1.3) which has begun to see implementation and adoption on the Internet [1, 2]. ECH seeks to allow encryption of the ClientHello message, which can contain potentially sensitive information such as the Service Name Indication (SNI) and Application-Layer Protocol Negotiation (ALPN) extensions. This is partially achieved through serving many private domains behind a common provider to form an anonymity set that conceals the true domain requested by the client.

Due to this, ECH introduces significant centralisation to the Internet. This paper presents a practical model for the distributed deployment of ECH amongst several co-operating TLS servers, where each server operates both as the origin server of its own domains as well as an ECH provider for other participating servers. The model addresses a number of implementation challenges, predominately related to ensuring the security of the protocol is not compromised and minimising the performance impact to the connection while strengthening service availability.

Included in this paper is a review of the background technology and concepts relevant to the discussion of the deployment model. This is followed by a study of the model's design and the complications which influenced it. We then see how this design can be implemented within a practical scenario and discuss some of its deployment considerations. In the subsequent chapter, an analysis and criticism of both the results taken from this implementation and the design as a whole is used to assess the quality of the solution. Finally, I conclude the report with a summary of the work completed and delineate where future contributions could best benefit the further development of the deployment model.

1.1 Motivation

Mark Nottingham has previously cautioned against the introduction of centralisation through Internet standards [3]. Of particular relevance to ECH is his highlight of the adverse effect centralisation can have on infrastructure resilience and service availability through

reliance on a single entity. This is especially detrimental to ECH where the effectiveness of its anonymity set grows with the number of private domains served by a single provider. Nottingham also writes on susceptibility of centralisation to stifle innovation and induce an unhealthy monoculture which may result in less overall technological progress and robustness of the ECH protocol.

Additionally, allowing entirely independent servers to co-operate from across the Internet to provide ECH support for each other enables several distinct organisations to work together to offer improved privacy for their users without the requirement for co-located servers nor the dependence of any on the availability of another. Consider here global networks of whistleblower services, investigative journalists and human rights non-profit organisations who share an interest in protecting the confidentiality of their members and users from persecution and retaliation.

For these reasons, the development of a model for the distributed deployment of ECH across several co-operating providers is a key step towards its application in <perilous> scenarios and broad adoption throughout the Internet.

1.2 Project Objectives

The objectives of this research project can be summarised with the following question: “How can Encrypted Client Hello be deployed fairly amongst co-operating Transport Layer Security servers to reduce network centralisation without compromising the security of the protocol?” This task is composed of the following objectives:

- 1. Identify principal challenges and appropriate solutions.** Before development can begin proper, we must first understand the environment the system would operate in and explore the technical and logistical issues it might face to determine the dominant criteria for design. We accomplish this through research and experimentation of the functioning of the protocol and its surrounding technologies.
- 2. Design, evaluate and contrast deployment models.** An iterative development process is used to produce a series of incrementally improved skeletal prototypes, with the goal to rapidly design and test for functionality guided by the design criteria and results of previous work as heuristics.
- 3. Analyse model implementations through simulation.** Promising design solutions are fleshed out into full implementations within deterministic, reproducible and quantifiable simulated environments, where security and performance implications can be easily isolated and compared. It is expected that unforeseeable practical challenges and considerations are to be unveiled during this work.

4. Conclude findings. <Learnings from comparisons> <As part of this, a prototype script is to be compiled from the implementation snippets>

In preparation for undertaking this project, I had produced the Gantt chart included in Fig. 1.2.1 to help gauge my progress during the four months of work. While I found more emphasis has been placed on implementation, the overall task structure of the timeline has been followed reasonable well.

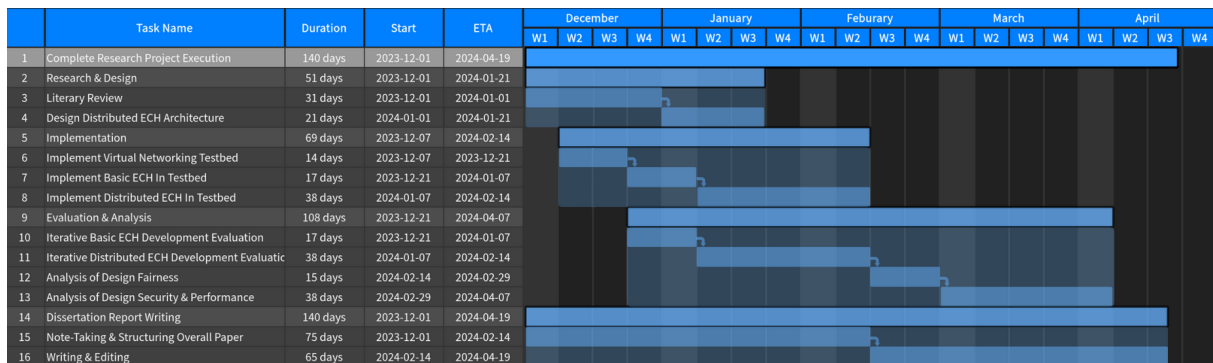

Figure 1.2.1: Predicted timeline of project as of the 7th of December, 2023

1.3 Research Contributions

This work provides evidence for the viability of the distributed deployment of ECH between co-operative TLS servers. It supports its argument that the deployment model presented does not compromise the security of the protocol and minimises impact to network performance though analysis of the data produced by implementations within simulated networking environments. Additionally, an evaluation of several traffic masking and normalisation techniques is given to serve as the bases for further work on disrupting traffic correlation attacks applicable to ECH and elsewhere. Finally, the delivered project may also contribute academic value as a deterministic, reproducible tutorial on the deployment and operation of ECH using commonplace software and tooling.

2 Background

This chapter offers an overview of the technology and concepts needed to understand the context and relevance of the work within the broader world. The review is conducted predominately through a networking, security and privacy perspective to best highlight the aspects pertinent to the distributed deployment of ECH. This chapter also represents the bulk of the effort put into investigating and studying the functioning of ECH while identifying and experimenting with different deployment models.

The contents of this chapter include a high level description of the Transport Layer Security protocol and the Domain Name System with a more detailed look at the components that enable ECH functionality. This is followed by an inspection of ECH itself, its security properties and the mechanisms which allow for distributed deployment. Finally, we survey how a variety of traffic analysis techniques that can be used to infer sensitive information from patterns in network activity, as well as the countermeasures which exist to mask these patterns.

2.1 Transport Layer Security

Transport Layer Security (TLS) is a cryptographic protocol proposed by the Internet Engineering Task Force (IETF) which enables secure network communication over public networks. Applications and services can establish an encrypted communication channel to transmit private information such that confidentiality, integrity and authenticity of the data can be ensured. TLS is commonly used to protect Internet traffic, having seen widespread adoption and several revisions since its original inception in 1999, superseding the Secure Sockets Layer (SSL) specification previously defined by Netscape Communications from 1994 [4–6].

TLS is designed to operate on top of a reliable transmission protocol between a client and server, such as the Transmission Control Protocol (TCP) when used over the Internet. In order to prevent eavesdropping, tampering and message forgery, TLS includes a number of security features based on a number of cryptographic mechanisms:

Confidentiality: All service and application data exchanged between the client and server is encrypted as to make it indecipherable to any intermediate party which might be intercepting their communication. For example, consider the importance of protecting customer passwords and banking information when accessing financial services.

Data integrity: In a similar manner, cryptographic properties are used to guarantee transferred data cannot be modified during transmission. This is critical for safeguarding against input manipulation in consequential situations, such as while conducting a monetary transaction.

Authentication: TLS provides the ability for both participants to verify the identity of the other, ensuring privileged communication is only performed with the intended recipient. Such a condition is fundamental for establishing trust and confidence in sensitive environments, as is required when interacting with online financial institutions.

TLS 1.3 is the latest defined standard for the protocol, having been published in August 2018 and contributing to the deprecation of TLS 1.0 and TLS 1.1 in March 2021 [7, 8]. <deployment stats>. It introduces many major changes to TLS 1.2, including the addition of a zero round trip time resumption (0-RTT) mode, further encryption and optimisation of the handshake and removal of outdated cryptographic algorithms and security mechanism with all key exchanges now providing forward secrecy. A change of particular relevance to ECH is the encryption of the digital certificate received by the client to authenticate the server.

2.1.1 Digital Certificates

TLS uses digital certificates to make assertions on the identity of entities within the network using a chain of trust model, and are of particular significance during the exchange of public keys. <what public key used for> <"the TLS connection handshake would be susceptible to man-in-the-middle attacks"> <therefore trust must be established>

<chain of trust model is a hierarchical structure of certificates, Fig 2.1.1> <ensures each certificate in the chain is issued by a trusted Certificate Authority (CA)> <root ca is inherently trusted> <These certificates contain public key, parent name, signature and other metadata>

<root ca typically installed by operating system> <it is possible to add your own>
<typically only server is authenticated, it sends its cert and public key during the handshake> <its certificate is verified by the client>

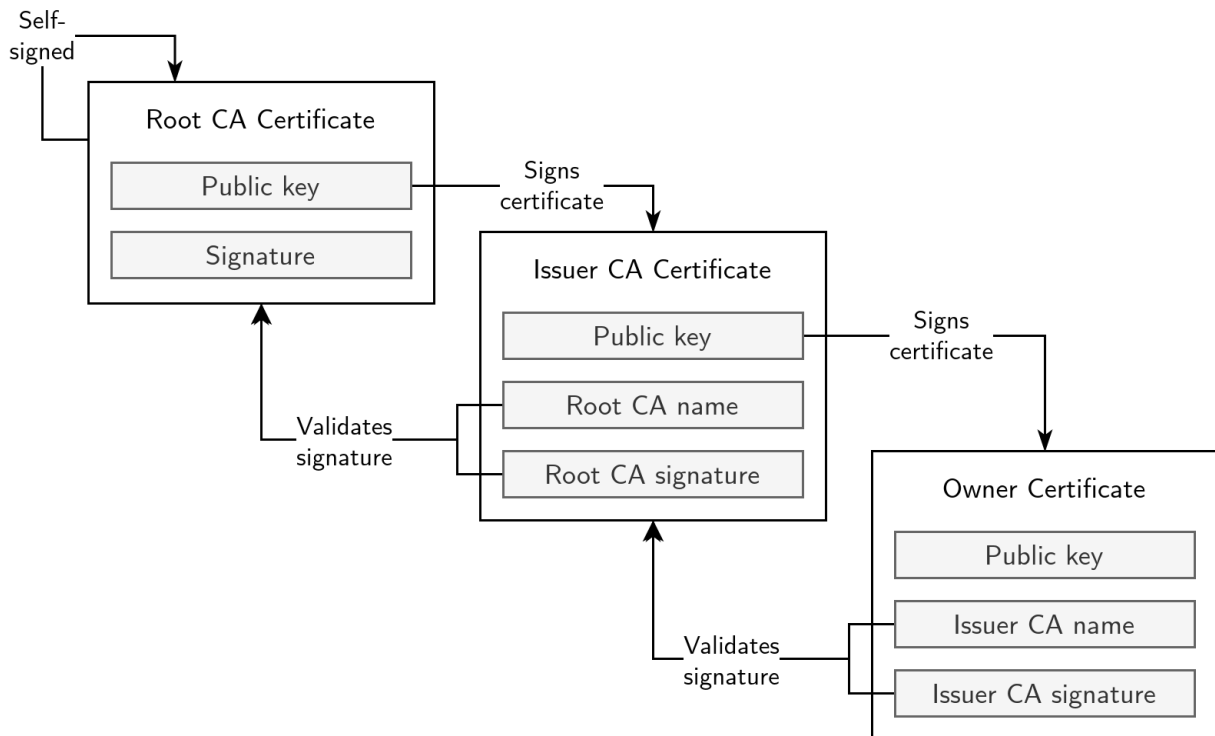

Figure 2.1.1: <>

2.1.2 TLS 1.3 Handshake

<the tls handshake is a procedure executed between the client and server to complete establishment> <tls 1.3 was designed to improve the security and performance of the handshake over 1.2 while reducing overall complexity> <Fig. 2.1.2> <application data>

<The handshake consists of a number of required and optional messages with some plain and others encrypted:>

ClientHello: <clienthello contents+purpose>

ServerHello: <serverhello contents+purpose>

Certificate: <optional certificate, now encrypted>

Finished: <finish protocol>

<in addition to these, the handshake offers extensions>

2.1.3 Extensions

<to remain adaptable, tls 1.3 permits numerous extensions to be inserted during the handshake for additional features and capabilities> <some are mandatory in 1.3 and others are very commonly used> <examples: ems, sni, alpn... and problems they solve> <wider

Figure 2.1.2: <>

range of use cases and accommodating evolving requirements> <examples: ech, ...>

<problems> <greasing>

2.2 The Domain Name System

<history of ip, why dns needed> <the domain name system (dns) was introduced to add alphanumeric domain names> <originally a big host file> <it now operates as a decentralised hierarchical naming system accessible by networked devices> <registration consists of a number of entities registrars, registrants, registries> <name server>

2.2.1 Name Resolution Process

<consists of root ns, tld ns, authoritative ns> <Fig. 2.2.1> <stub resolver queries local recursive resolver> <if not cached, asks root-tld-etc>

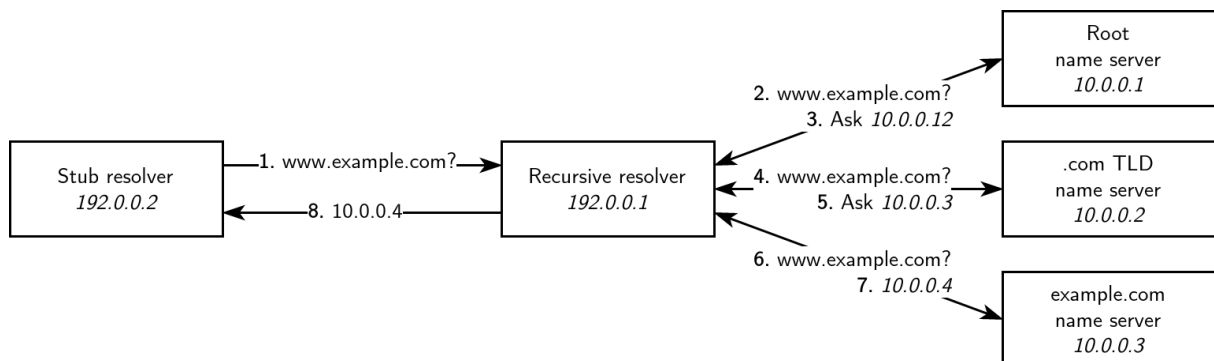

Figure 2.2.1: <example dns query resolution process for www.example.com>

<dns protocol>

2.2.2 DNS Over HTTPS

<security was previously not a concern as the information was considered public> <passive attacks considered bad [todo]> <introduction of dot> <problems> <introduction of doh> <doh security>

2.2.3 The HTTPS Resource Record

<these days a number of resource records exist for more advanced functionality and adaptability> <new rr have been added to support performace and some fixes[https-rr]> <this has also allowed additional data to be accociated with a host> <ech uses this as the primary mechanism to transmit echconfig out-of-band to clients>

2.3 Encrypted Client Hello

<why need ech> <what ech is "Encrypted Client Hello (ECH) is a proposed extension for TLS 1.3 which has begun to see implementation and adoption on the Internet [1, 2]"> <what ech does "ECH seeks to allow encryption of the ClientHello message, which can contain potentially sensitive information such as the Service Name Indication (SNI) and Application-Layer Protocol Negotiation (ALPN) extensions." <how ech does this "This is partially achieved through serving many private domains behind a common provider to form an anonymity set that conceals the true domain requested by the client.">

The client-facing server first generates an ECH encryption key pair and some associated metadata. This public key and metadata, referred to as an ECH configuration or ECHConfig, may then be shared out-of-band to ECH-enabled clients though secure means like DoH. A client may then use this to construct a ClientHello message, named the ClientHelloOuter, holding unremarkable values for the client-facing server along side an encrypted ClientHello, named the ClientHelloInner, itself holding the real values for a private domain. To establish a TLS connection to the origin server of this domain, the client sends the ClientHelloOuter to the client-facing server, which decrypts and relays the contained ClientHelloInner to the origin server, which itself completes the TLS handshake with the client through the client-facing server.

<in this way, the true domain is concealed>

2.3.1 Hybrid Public Key Encryption

<much like tls itself, the ech extension uses public key cryptography> <HPKE explanation>

2.3.2 Split Mode Deployment

<ech defines two modes of network topology> <shared mode is when the client-facing server and backend server are co-located, and is not of interest to us> <split mode is when the client-facing server and backend server are in different boxes physically separated> <Fig. 2.3.1>

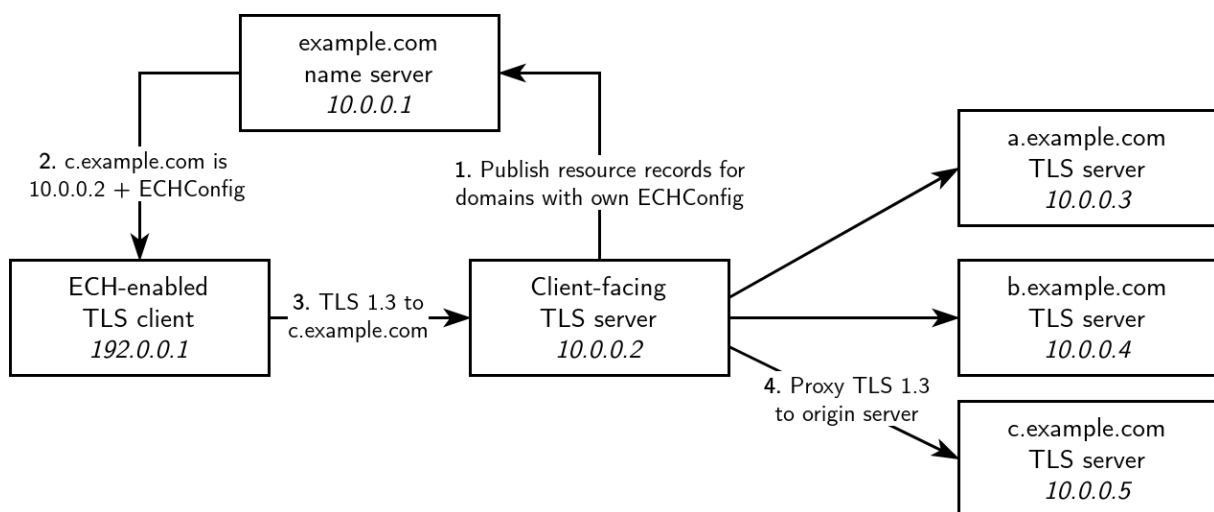

Figure 2.3.1: <>

<this is useful for x,y,z...> <distributed deployment explanation (as opposed to centralised and decentralised)> <however it is susceptible to attacks>

2.4 Traffic Analysis

<what is traffic analysis> <traffic analysis techniques that can be used to infer sensitive information from patterns in network activity> <exploits information unintentionally leaked by the system aka side-channel attack> <example of the act of communication being information itself> <there are a lot of other techniques that can be used: packet inspection>

2.4.1 Correlation Attacks

<is a large category of attacks identified by correlating communication patterns> <can be used to break anonymity, very relevant to ech split mode> <examples: timing, packet size, packet count, packet rate+pattern>

2.4.2 Countermeasures

<to disrupt the patterns> <effectiveness against practicality> <examples: morphing, mixing/pacing and padding, normalisation>

2.5 Summary

<tls and dns continue to evolve with shifting requirements> <ech has been enabled due to this, which allows for the encryption of the clienthello> <ech split mode permits the client-facing server to be physically separate from the backend server> <this reveals potentially attack surface through traffic correlation, which must be distributed with various countermeasures>

3 Design

<during the course of this project, a <to complete this project, a carefully considered design must be investigated and refined>

<this consists of identification of likely challenges which influence the architecture of the solution> <in this chapter, a >

6 Conclusion

<this research has been a first effort to create a distributed ech deployment model> <we have seen background> <we have seen design> <we have seen implementation> <we have seen results>

<in this final chapter, present key learnings> <then outline future work> <finish with a reflection of the project as a whole>

6.1 Learnings

<ECH Split Mode topology permits distributed deployment> <https rr enable static load distribution> <A dynamic DNS service allows for fair load distribution> <minimal performance impact when compared to normal> <security is ok and techniques exist to defend against correlation attacks>

6.2 Future Work

<shared dns publication strategy (with ech key rotation)> <dynamic traffic flow analysis for load balancing (instead of just distribution)> <more in-depth study on disrupting traffic correlation attacks> <test deployment on actual hardware with realistic traffic>

6.3 Reflection

Hello, here is some text without a meaning. This text should show what a printed text will look like at this place. If you read this text, you will get no information. Really? Is there no information? Is there a difference between this text and some nonsense like “Huardest gefburn”? Kjift – not at all!
